The ability to digest lactose and milk sugar is learnt and "picked up" by adults in their 20s and 30s, after which they are permanently "hard wired" into the gut. Researchers from the University of California conducted a study of 10,000 baby gut microbiomes. The team tracked the

composition of the infants' guts over time. Its results, published in the journal Scientific Reports, show that the mixture of bacteria in a "gut microbiome" is so variable at birth that it resembles the adult gut microbiome in every way. "It was a bit surprising in the beginning," says Patrick Schloss, who co-led the study. "We found that the same holds true after one year of age. "Already, by a year of age, there are major differences between the microbiomes of infants that were breast-fed versus those that were formula-fed," says Dr Schloss. Professor Stefan Schinkinger, also from the University of California, says that this is the first comprehensive analysis of early-life influences on the composition of an individual's microbiome. "Since the human gut is thought to be a window on the rest of the human body, this is really interesting and should lead to a better understanding of human health," he told BBC News. Bacterial build-up In the next few years the team will also be able to identify babies who are at risk of developing allergies or obesity. "The study of our day-old infants showed that a substantial amount of variation between babies is determined at birth," explains
